Category:Microsoft product lines References Category:Windows Server Category:Windows 8The Solar System and Life on Earth What Start polar planet orbital path Celestial bodies Celestial bodies are spherical masses of matter around which orbiting bodies, such as planets, moons, and stellar bodies (including the Sun), rotate or orbit. The mass of a celestial body is usually designated by the prefixes Kilogram and Terrestrial. An orbit is a closed curve about a celestial body that contains a minimum point called a perigee and a maximum point called an apogee. The distance from a celestial body to its orbit is called its mean distance. A celestial body may be fixed on the sky with an orientation that fixes a prime vertical. If it is rotating, then the orientation determines a pole. The resulting figure is called the celestial body's celestial equator and meridian. The celestial equator and meridian on the top surface of the celestial sphere have a fixed separation from the celestial poles. The celestial poles are separated by a degree of longitude. The celestial equator and meridian are separated by the same amount of latitude. The mean distances to other terrestrial planets varies from just 0.22 astronomical units for Mercury to 45.3 astronomical units for Neptune. Mean distances vary as the square of the distance from the Sun. The Sun is the farthest from the Earth at 1 astronomical unit. Planetary motion is considered to be Keplerian if it is a succession of great circles on a sphere. The motion of the planets is considered to be circular if it is a succession of great circles on the surface of a sphere. Because of the surface curvature of the celestial sphere, we should remember that some great circles are actually arcs. The length of an arc as measured from the pole of the terrestrial plane to its terminator (called the solar polar radius) may vary from about 9.2 million kilometres to 11.2 million kilometres. An object in orbit is a body that spends part of its time orbiting a celestial body.
