We report a case of secondary hematoma of the spleen complicated by HELLP syndrome in a 33-year-old female. A splenic artery aneurysm was demonstrated by selective angiography. The condition was diagnosed as a splenic artery aneurysm because computed tomography showed an aneurysm of the splenic artery and thrombocytopenia with a platelet count of 8,000/microL and hypofibrinogenemia (1.3 mg/dL) were observed. The patient was successfully treated by laparotomy and splenectomy. Cyclin-dependent kinase inhibitor p27(Kip1) is decreased in human retinoblastoma. Human retinoblastoma was studied at the cell cycle level to investigate the relationship between the tumor cell cycle status and the potential for expression of the cyclin-dependent kinase inhibitor p27(Kip1). Normal retinal tissues and primary retinoblastoma tumor tissues were analyzed for p27(Kip1) expression with immunohistochemistry and Western blotting. The results demonstrated significantly less p27(Kip1) expression in retinoblastoma tissues. This data suggests that a decrease in p27(Kip1) expression may play an important role in the pathogenesis of retinoblastoma. Molecular cloning and expression of the gamma-1 subunit of the voltage-dependent calcium channel from rabbit heart. We have isolated and cloned cDNA for the gamma-1 subunit of the rabbit alpha-1-delta(1) L-type Ca(2+)-channel from rabbit heart. We have found that a poly(A)+ RNA of 1710 nucleotides (nt) can encode a 370 amino acid protein of approximate Mr of 40,000. According to nuclease protection assays we have isolated two poly(A)+ RNA species of 1470 and 2230 nt, the latter of which encoded the complete coding sequence. In total, the sequence cloned comprised 1746 nt and contained an open reading frame of 1425 nt encoding a protein with 486 amino acids. Sequence analysis of the novel gene revealed strong homologies to other gamma-subunit genes from different species. Like all
