Our front-end React application will now compile into a readable JS file. Now, we will open our front-end/src/index.js file and make a small change to add some ES6 classes to our application. We will simply import the Javascript file and store it as a variable on the App object. One small change we will make is to add an arrow function definition on our App constructor. The constructors function will be able to get context from an this that will act on a global this and be able to access the site's router variable and fetch information from the params. In our Application.js file we will add some functionality to make sure our application is up and running. We will add our route and a function called loadData. Our loadData function will look at the parameters and make sure we are logged in using the Auth class. We have two parameters to our function, one for the name of the route and one for the parameters. We create a new mountable component called Auth with a name of Auth to use as a data component in our Application.js file. We will have our user's current userId to the user as a variable on the Auth component. We will assign the data component and pass it the userId that we have and check to make sure we are logged in. When the userId is authenticated we will then dispatch a fetchData action that will use Redux to make sure fetching the data is not done if we are not logged in. We will not use the dispatch action inside our React application for changes to our application state.

In Vue CLI there is a quick shortcut to generate a new vue-cli project. Simply enter the vue init command and name your project Content-Types-Builder. Then navigate to the newly created folder that was created and enter the command npm install to install your dependencies. Press the y to confirm your installation and type y again to confirm you agree to the license. In your root vue-cli project directory enter the command npm run dev which will build the application for you and open a dev console that you can use for experimenting. You can test out the CRUD functionality by editing the /src/store/actions.js file and adding a new action to our vuex store called addArticle. Add the following code below to the actions file. export default { mutations: { }, actions: { addArticle(context) { context.commit("addArticle", { title: 'Content Type Example' }); } } } }

 In the Vue CLI the index.html page is generated for you when you generate a new project. The file is located in the src/index.html and is the starting point where you should add the vue-server-renderer tags which allow you to build your application. You can also add the vue-cli-service style and script tags that will load your CSS and javascript assets. You should also add the tag if it is not already present. You should also add in order to support the browsers that read the tag. If you are using a proxy you can run the command vue-cli-service build --prod --proxy to tell the proxy to direct all requests to the development and production servers. After you have added the tags the page should look like the following.
