The aim of this in vivo study was to evaluate the clinical performance of implants with an internal metal-ceramic connection for single-tooth restorations. Ten implants were placed in the interforaminal area of the mandible in two similar arches. One with a titanium-zirconium/ceramic connection and the other with the PowerLink system. Marginal and marginal accuracy at implant level, at abutment level, and at implant-abutment interface were measured. Internal fit was evaluated by means of a silicone replica technique. After a mean healing period of 4 months, the follow-up (mean time: 5 months) was performed at implant level. Marginal fit and marginal accuracy of implants were not influenced by internal interlocking. No differences were observed between metal-ceramic and PowerLink implants. A mean marginal discrepancy of 0.36 mm and a mean retention loss of 2.4% were observed. Internal fit at abutment level was good for both systems and was not influenced by the power setting. However, the titanium-zirconium/ceramic connection showed a smoother surface at the implant-abutment interface than the PowerLink system and a slightly better marginal fit. From the results, it is concluded that both systems are not significantly different in terms of survival rate, marginal, and internal fit in single implants for both arches.The effect of a high-calorie diet on mouse intestine. In this study, the effects of feeding a high-calorie diet on the morphology and the various functions of the mouse small intestine are investigated. When given a standard food and water supply a fecal weight gain of 25 to 30% of body weight is attained after 3 to 4 days on the diet. In contrast, when mice are kept on the diet for 4 weeks the body weight rises only slightly, and the feces are changed to a consistency resembling a spongy mass. This difference between 1 week and 4 weeks on the diet is, at least in part, due to an 79a2804d6b
