The invention relates to a drive for a camshaft of an internal combustion engine, which has a toothed belt drive from a motor unit to the camshaft. Toothed belt drives have various advantages with respect to gear and chain drives. In particular, a belt drive has a higher load-bearing capacity than a gear drive, and is less susceptible to soiling, and is quieter than a gear drive. For these reasons, it is used quite extensively. In a belt drive, the motor unit and the camshaft are mechanically connected to each other by means of a toothed belt. When the motor unit rotates in one direction, a tooth of the toothed belt forms a helical route along the camshaft and causes the latter to rotate. On the other hand, when the motor unit rotates in the other direction, a tooth of the toothed belt returns along the camshaft, and so causes the camshaft to rotate. As a rule, a toothed belt comprises elastically deformable carrier and drive elements. This deformability enables the belt to function reliably even if it is wet. Furthermore, the belt is usually mounted on a metal carrier in such a way that it is secured against slipping with respect to the carrier, which enables a permanently accurate position of the belt on the carrier. Depending on the engine requirements, the camshaft is driven by a toothed belt at a speed higher or lower than the speed at which the motor unit rotates. In most cases, the relation between the two speeds is one-to-one, namely the rotation speed of the camshaft corresponds to the rotation speed of the motor. In other words, a gear ratio of 1:1 is set between the camshaft and the motor unit. This gear ratio is set by suitable choice of the teeth of the camsh
