Algebraic notation Algebraic notation is a notation for groups, rings, semigroups, and vector spaces, or modules over a ring. It is based on the properties of the corresponding object, and its proof theory is algebraic in nature. Algebraic notation for groups is known as the identity calculus. The two most common notations are plain group notation and group-ring notation. Group-ring notation Group-ring notation for a group G is characterized by the fact that the group operation is written multiplicatively, so that the symbol denotes the product of two elements g and h of G . For example, the group G of order is written $G(a, b, c, d, e, f)$ in this notation. A natural operation of addition is defined on G , by the rule: For example, since G has an identity element, the addition identity element e can be written. To use this notation in a statement, a proposition or a proof, the first element is written as a lowercase letter with a subscript, and the rest are denoted by greek lowercase letters. For example, g denotes the identity element in G , and. Groups with an operation with multiple arguments, such as the group of matrix inverses, need to be specified more clearly. One convention is to use the letters A , B , C , and D for arguments, with the first element in the argument repeated as many times as necessary. For example, in the group of invertible matrices with complex numbers as coefficients, the matrix A^2 denotes. Group-ring notation Group-ring notation for a group G is also called the identity calculus, since it is essentially based on the properties of the identity element. The fact that the inverse of a group element is the same as its group inverse has a number of important consequences. For example, if A is a $-by-$ matrix with complex numbers as its entries, then the matrix has the properties that its determinant is, its inverse is.
